Preface

Inorganic Substances Bibliography 2016

The "Inorganic Substances Bibliography" tries to give a "quantitative" overview of relevant publications on physics and chemistry of inorganic substances. In contrast, the companion publication "Handbook of Inorganic Substances" is based on a qualitative approach, i.e. all the included data having passed a quality check.

This handbook is a product of the PAULING FILE project[1] (see below). By browsing approx. 10 000 000 scientific publications, primarily in a "cover to cover approach" of about 200 major journals, we have selected some 200 000 publications containing data belonging to one of the following fundamental materials research fields: crystallographic structures (S), phase diagrams (also called "constitution") (C) and the large field of intrinsic physical properties (P). This work has been done systematically starting with literature year 1900. During the browsing process, we have noted the above mentioned research field codes (S, C, P), as well as the chemical systems investigated in each publication. The aim of the Inorganic Substances Bibliography is to provide researchers and students with a comprehensive compilation of published scientific publications on inorganic substances released at present as e-book within 23 parts.

Each distinct combination chemical system – literature reference is represented by one row containing selected information.

How to read the Bibliography

El.-System	Source	Codes	First Author	Title
Ag-Al-Br-O-Si	JACSAT,1992,114, , 5171,5186	S	Stein A.	Silver, Sodium Halosodalites: Class A Sodalites
Alphabetically sorted chemical elements	Source, given in this order: CODEN, year, volume, issue/article,	Research field code (C, P, S)	First author of the publication	Title of the publication, truncated after approx. 80 characters

C: publication containing phase diagram data
P: publication containing intrinsic physical property data
S: publication containing crystal structure data (at least cell parameters)

Table 1 Content of the main table.

The short document name used here uniquely defines the scientific publication. The user can find a table listing over 1500 CODENs and the corresponding abbreviated journal names after the preface.

The data is sorted in first priority according the number of chemical elements in the chemical system, in second priority in alphabetic order of the chemical system, in third priority according to the year of publication, and in fourth priority according to the complete reference. The letter R has been used to indicate a rare-earth element.

The 466 700 combinations chemical system literature reference (rows), selected approx. 243 000 publications, represent more than 86 000 chemical systems. The distribution is as follows:

Number of chemical elements	Number of chemical systems	Number of combinations chemical systems – literature references
1	101	11 392
2	3 135	106 268
3	22 746	170 158
4	28 717	110 324
5	19 445	47 857
>5	11 959	20 701
Total	86 103	466 700

Table 2 Correlation between the number of chemical elements, chemical systems and references.

About 10 000 new scientific publications are selected yearly. This generates near 20 000 additionswal rows annually. Each new edition will contain the data of the preceding edition and incorporate recent references, as well as some additional older references.

PAULING FILE project

One of the most challenging tasks in materials science is the design of new materials with distinct properties. In general, two different approaches are explored:

1. The first one is to simulate the motion of the atoms in the material as well as their electronic interactions as close to reality as possible by using calculations on the quantum-mechanical level. This is an extremely demanding task, especially if the calculation of the property under investigation requires a long-time simulation. However, at least in theory, there is no input other than the laws of quantum mechanics, so using these calculations the material properties can be understood immediately from *first principles.* Based on this understanding, it should be possible to design new matrials with distinct properties just through computer simulations.
2. The second approach seems to be less challenging at first glance, since it does not entail the really fundamental principles but remains on a more pragmatic level: Most of our current knowledge in chemistry and material science has been collected *empirically*, just by searching for patterns and rules in experimental results published in literature. During the past 100 years or so, a huge pile of various types of corresponding data like crystal structures, powder diffraction patterns, phase diagrams and physical properties has been collected for a large variety of compounds. This information is mainly available in various materials databases.

Besides the classical use of these databases for analysis, phase identification and teaching purposes, it should be worthwhile implementing the use of modern computer technology to search for additional rules and correlations implied in this data and use them in materials design.

Both approaches have their own advantages and problems: While the first one does (at least in principle) not rely on experiments and should result in a really deep understanding of fundamental correlation in solids, it is computationally extremely demanding and can currently only be applied to a limited number of rather simple solids. The second approach needs by far less computational effort and may thus (at least in the beginning) lead to faster success; however, it is extremely depending on the availability of a sufficiently large number of experimental data of appropriate quality. An additional problem concerning this second empirical approach is that, up to now, the relevant data types have been stored in separate, isolated databases, each using its own proprietary retrieval software. This made the investigations rather tedious and prohibited the user from performing an overall data analysis in order to discover hidden patterns and correlations.

These shortcomings of the empirical approach provided the basic motivation for the initiation of the PAULING FILE project, which started in 1995 as a collaboration between Japan Science and Technology Corporation (JST), Material Phases Data System (MPDS), and The University of Tokyo, RACE. Since 2002, the project is under the leadership of MPDS.

The first goal is to create and maintain a comprehensive materials database for all non-organic (no C-H bonds) solid state materials (systems), covering crystallographic data, phase diagrams, diffraction patterns and physical properties. An important aspect, along with completeness, is the quality of the data. The data have been checked with extreme care, since unrecognized errors will at least confuse the correlation tools, if not result in wrong rules that may be deduced.
